### INTERPRETATION:

This is a 18 channel routine EEG. The EEG recorded under standard condition using 10-20 international system of electrodes placement. Recording began with machine calibration and bio-calibration.

The patient was sedated asleep.

The background activity showed 7-8Hz theta activity intermixed with 1-2Hz delta activity superimposed by 12-14Hz beta activity in a diffused manner, vertex waves and sleep spindles were also noted.

During recording generalized spike and slow wave activity were noted.

Attempts were made to awake the patient by auditory and somatosensory stimuli on which the patient became awake and no significant changes in background activity except muscle and movement artifacts.

Hyperventilation was not done due to age of the patient.

Intermittent photic stimulation was unremarkable.

Muscles, movements, eyes movements, electrodes pops and 50Hz artifacts were also noted.

### IMPRESSION:

This is an abnormal EEG in view of intermittent generalized spike and slow wave activity.

### CONCLUSION:

This is an abnormal EEG findings are suggestive of seizure activity. Neuro-Imaging and further clinical correlation is advised.
